

Metric Symmetry by Design

**A Lagrangian perspective with
computer algebra adventures**

Historical origins

- **The Einstein-Hilbert Lagrangian**

$$S = \int d^4 x \sqrt{-g} (R - 2\Lambda) + S_{\text{matter}}$$

- **The corresponding Euler-Lagrange field equation is Einstein's field equation:**

$$R_{\mu\nu} - \frac{1}{2} R g_{\mu\nu} + \Lambda g_{\mu\nu} = 8\pi G T_{\mu\nu}.$$

- **But how is it derived?**

The canonical route

- **Lagrangian with second derivatives**

$$\frac{1}{\sqrt{-g}} \left[\frac{\partial \mathcal{L}_{\text{grav}}}{\partial g_{\mu\nu}} - \frac{\partial}{\partial x^\kappa} \frac{\partial \mathcal{L}_{\text{grav}}}{\partial g_{\mu\nu,\kappa}} + \frac{\partial^2}{\partial x^\kappa \partial x^\lambda} \frac{\partial \mathcal{L}_{\text{grav}}}{\partial g_{\mu\nu,\kappa\lambda}} \right] + [\text{matter terms}] = 0.$$

- **Higher derivatives appear only linearly as total derivatives, so we avoid the Ostrogradsky instability**
- **Field equations remain second order**

Suitability for computer algebra

- **Straightforward derivation involving field derivatives**
- **No “magic”, no heuristic assumptions, just deterministic steps**
- **Can a CAS handle the abstract index formalism efficiently?**

MACSYMA, Maxima and itensor

- **MACSYMA – one of the oldest CAS, oldest in active development**
- **Open-sourced (thanks to the late William Shelter) as Maxima around 2000, in active development since**
- **Contains dedicated tensor algebra and calculus packages**

Indexed tensors in CAS

- **Maxima's itensor takes the abstract index formalism literally**
- **Tensors are opaque objects, manipulated without coordinate-dependent representation**

A few examples

- $S([\], [\])$ is a scalar field
- $V([\], [a])$ is V^a , a vector field
- $V([\], [a], b)$ is its coordinate derivative with respect to x^b
- $T([a], [b, c])$ is a rank-3 tensor, T_a^{bc} .
- Built-in primitives/representations for the curvature tensor and Christoffel-symbols
- Recognizing symmetries and contraction rules
- Ability to represent a frame base

Algebraic capabilities

- Flexible symmetry property declarations
- Powerful simplification makes it easy to prove many identities

Variational calculus

- **The action principle is based on variational calculus**
- **Formal derivation of field equations or equations of motion requires functional differentiation**
- **Capability was absent in itensor prior to 2005**

A simple example

- **Scalar field theory,** $\mathcal{L} = \frac{1}{2} \eta^{\mu\nu} \varphi_{,\mu} \varphi_{,\nu} - \frac{1}{2} m^2 \varphi^2$:

```

          - F m - F h
          ,%1 %2
(%i5)

```

- Which of course we recognize as the field equation $(\nabla_{\mu} \nabla^{\mu} + m^2) \varphi = 0$.

Another example: Maxwell

- Derivation of Maxwell's equations from the EM Lagrangian
- The derivation is valid even in curved spacetime

```

Gravitational theories

- The metric is present as a field but also as the integration measure of the action integral
- Maxima can properly deal with terms like $\sqrt{-g}$ in the integrand
- Deriving the EFE from the Einstein-Hilbert Lagrangian should be easy

Let us do the derivation

```
load(itensor);
imetric(g);
remcon(g);
defcon(g,g,kdelta);
components(R([a,b,c,d],[ ]),
            (canform(isimplify(ev(icurvature([a,b,c],[e])*g([d,e],[ ]),ichr2,eval))))))$
components(R([a,b],[ ]),(canform(isimplify(ev(icurvature([a,b,c],[c]),ichr2,eval))))))$
components(R([ ],[ ]),(canform(isimplify(ev(icurvature([a,b,c],[c])*g([ ],[a,b]),ichr2,eval))))))$
L0:ishow(1/(16*pi*G)*((2*L+'R([ ],[ ])))*sqrt(-determinant(g)))$
L0:(isimplify(ev(L0,R,eval)))$
EL0:isimplify(diff(L0,g([ ],[m,n])))$
EL1:isimplify(-idiff(diff(L0,g([ ],[m,n],k)),k))$
EL2:isimplify(idiff(idiff(diff(L0,g([ ],[m,n],k,l)),k),l))$
EL:(isimplify(expand((EL0+EL1+EL2)*16*pi*G/sqrt(-determinant(g))))))$
EFE:ishow('R([m,n],[ ])-1/2*g([m,n],[ ])*'R([ ],[ ])-L*g([m,n],[ ]))$
EFE:(isimplify(ev(EFE,R,eval)))$
D:isimplify(contract(isimplify(ev(EL,ichr2,eval))-rename(EFE)))$
```

Nice and clean...

```

What about symmetries?

- In the calculation so far, we assumed nothing about $g_{\mu\nu}$.
- The metric tensor is supposed to be symmetrical:

```
CORE <@core.vttoth.com>
(%i19) line1:80$decsym(g,2,0,[sym(all)],[]);
(%o20) done
(%i21) decsym(g,0,2,[],[sym(all)]);
(%o21) done
(%i22) ishow(isimplify(contract(isimplify(D))))$
(%t22) 0
(%i23) █
```

Configuration space

- Of course... the “configuration space” is restricted to symmetric metrics only
- But the variational principle does not “know” this
- We introduce symmetrization “by hand” at some point, whenever convenient
- But this is neither rigorous nor robust

A naive example

- **Object falling in homogeneous gravitational field with lateral freedom of motion:**

$$L = \frac{1}{2} m (\dot{x}^2 + \dot{y}^2) - mgy .$$

- **The corresponding Euler-Lagrange equations are straightforward:**

$$\begin{aligned} m \ddot{x} &= 0 , \\ m \ddot{y} &= -mg . \end{aligned}$$

- **But this is free fall.**

A naive example (cont'd)

- What about sliding down an incline?
- We just changed the “configuration space” confining the solution to $dx = dy \tan \varphi$
- We could thus modify our equation of motion “by hand”:

$$m(1 + \tan^2 \varphi) \ddot{y} = -mg.$$

- But this is not really the “right” way, is it.

The power of the Lagrangian machinery

- The textbook solution: add a Lagrange-multiplier!
- Doing so “informs” the variational principle about the correct configuration space:

$$L = \frac{1}{2} m (\dot{x}^2 + \dot{y}^2) - mgy + m \lambda (x^2 - y^2 \tan^2 \varphi).$$

- As a result, the right equations of motion are produced automatically:

$$x = y \tan \varphi ,$$
$$m (1 + \tan^2 \varphi) \ddot{y} = -mg .$$

The case of metric symmetry

- The symmetry constraint is $g_{[\mu\nu]} = 0$.
- Conceptually, it is similar to the “inclined plane” constraint in the simple example
- It restricts the “configuration space”
- Why apply this constraint *post hoc*, instead of informing the Lagrangian machinery up front?

Why not just symmetrize?

- We could, of course, use the substitution, $g_{\mu\nu} \Rightarrow g_{(\mu\nu)}$, in the Lagrangian used in a CAS
- This was my first approach, when I treated this as basically just a “software problem”
- Nastier than it sounds: the substitution has to be tracked through the curvature tensor, the integration measure, the connection
- Feels brittle, fragile, *ad hoc* in any case

A Lagrange-multiplier

- How about following instead the canonical approach?

$$S = \int d^4 x \sqrt{-g} (R - 2\Lambda + \lambda^{\mu\nu} g_{[\mu\nu]}) + S_{\text{matter}}$$

Variation with respect to λ

- Variation with respect to the nondynamical Lagrange-multiplier is straightforward:

$$g_{[\mu\nu]} = 0.$$

- Exactly what we wanted in the first place.

What about the EFE?

- This is where things get interesting:

$$R_{\mu\nu} - \frac{1}{2} R g_{\mu\nu} + \Lambda g_{\mu\nu} + \lambda_{[\mu\nu]} = 8\pi G T_{\mu\nu}.$$

- Given that the first three terms are now manifestly symmetric, we can rewrite this as

$$R_{\mu\nu} - \frac{1}{2} R g_{\mu\nu} + \Lambda g_{\mu\nu} = 8\pi G T_{(\mu\nu)},$$
$$\lambda_{[\mu\nu]} = 8\pi G T_{[\mu\nu]}.$$

Verification using Maxima

```

```

What does it mean?

- If the matter stress-energy tensor is symmetric, nothing.
- However: gravity does not constrain matter to have a symmetric stress-energy tensor.
- In fact, gravity is not at all sensitive to antisymmetric contributions.

But wait...

- We have $T^{\mu\nu} = (-2/\sqrt{-g}) \delta S_{\text{matter}} / \delta g_{\mu\nu}$
- If $g_{\mu\nu}$ is constrained to be symmetric, doesn't that imply the symmetry of $T^{\mu\nu}$?
- But recall, unless we vary with respect to $g_{(\mu\nu)}$, we vary 16 degrees of freedom independently
- E.g., if the matter action contains the scalar product of two vector fields, the result will not be symmetrical.

Canonical example

- The conserved angular momentum current is

$$J^{\lambda\mu\nu} = x^\mu T^{\lambda\nu} - x^\nu T^{\lambda\mu},$$
$$\nabla_\lambda J^{\lambda\mu\nu} = 0.$$

- If $T^{\mu\nu}$ is conserved, we have

$$\nabla_\lambda J^{\lambda\mu\nu} = 2T^{[\mu\nu]} = 0,$$

so the symmetry is assured.

Spin current

- **But the presence of a spin current changes the picture:**

$$J^{\lambda\mu\nu} = x^\mu T^{\lambda\nu} - x^\nu T^{\lambda\mu} + S^{\lambda\mu\nu}$$

- **Since typically, $\nabla_\lambda S^{\lambda\mu\nu} \neq 0$, conservation of angular momentum no longer implies $T^{[\mu\nu]} = 0$.**

Examples

- **Canonical case: spinor field**

$$S^{\lambda\mu\nu} = \frac{1}{2} \bar{\psi} \gamma^\lambda \Sigma^{\mu\nu} \psi.$$

- **Torsion in Einstein-Cartan theory is related, but distinguish between symmetries of the Lagrangian functional vs. the variational degrees of freedom**

Belinfante-Rosenfeld tensor

- The problem is “cured” by introducing a symmetrized stress-energy tensor

$$\Theta^{\mu\nu} = T^{\mu\nu} + \frac{1}{2} \nabla_{\lambda} (S^{\mu\nu\lambda} + S^{\nu\mu\lambda} - S^{\lambda\mu\nu}).$$

- This is usually justified by observing that what remains is precisely the stress-energy tensor of the EFE
- This justification becomes unnecessary in our formalism.

Some concluding thoughts

- **A CAS can serve as a powerful consistency checker**
- **The symmetry of the stress-energy tensor is not enforced by gravity**
- **It is imposed on the matter side (e.g., isotropic perfect fluid in FLRW)**
- **Far from this idealized regime (early universe?) there may be tangible implications**

Summary

- A “simple” CAS problem: Why is it so hard to reproduce the derivation of the EFE from the EH Lagrangian?
- Post-hoc imposition of metric symmetry works but feels “dirty”
- Introducing the constraint up-front in the Lagrangian is the rigorous approach
- Doing so by way of a Lagrange multiplier leads to interesting results.
